AUTHOR: Voronca, A., Engineer

TITLE: The application stage of geophysical methods in drilling holes for the exploration and determination of the reserves of coal deposits in the USSR

PERIODICAL: Revista Minelor, v. 11, no. 11, 1960, 501 - 506

TEXT: The USSR widely uses the geophysical sampling for the exploration of coal deposits, performing yearly more than 3.1 million geophysical samplings. The drilled holes are examined by electric and radioactive sampling and many samples are extracted by the sidewall sampler for the determination of the stratigraphical columns and detection of coal. The used electric sampling methods are: apparent resistivity (KS), self-potential (PS), gradient of self-potential, produced potential (VP), bridge resistance (MC), electric currents (TK), and sliding contacts (MSC). The radioactive sampling methods are: natural gamma (GC), neutron-gamma (NGC) and gamma-gamma (GGC). The soil samples are taken with the sidewall sampler, which extracts 20 samples in one operation. The volume of a sample varies between 1 - 5 cu cm. Geophysical research conducted at a scale of 1 : 200

The application stage of geophysical methods ...

serves for the detection of coal, completion of the stratigraphical columns and lithological horizonting of the profile. Geophysical research conducted at a scale of 1 : 50 serves for the determination of thickness and structure of coal strata. Electric sampling methods are used for the study of coal deposits in which the electric parameters of the coal are clearly distinguished from that of the other rocks, or rocks of similar parameters, but of non-important quantity. The detection of coal is accomplished by the KS and TK methods, and for details the VP and PS methods are used. An accurate quantitative interpretation is accomplished by the PS gradient method. Coals of high resistivity, i.e., the majority of the deposits of Donbas, Kuzbas, Pechora Basin, Karaganda, Lvov-Volyn, Sakhalin Island, etc., as well as the anthracite coal deposit of the Donets Basin are detected by these methods. The radioactive methods combined with electric methods are used for the detection of mineral coal and lignite deposits with a high electric resistivity, and lignite deposits with a high content of ash. The used radioactive methods are GC, NGC and GGC. The latter method was introduced by the USSR in 1955, supplying at present the best results in the detection of the coals in drilling holes. For details, the radioactive methods are completed by KS and PS electric measuring, rarely by TK and gradient PS methods. The coal deposits of Kizelo and Chelyabinsk, as well as some deposits of the Moscow basin are examined by radio-

The application stage of geophysical methods...

active methods whereas the coal deposits of the Western Urals, some sections of the Donets and Moscow basins and of the Tomi-Usink Region in Kuzbas are detected by the combined method. The use of a complex geophysical process expanded by the sidewall sampling method, guarantees the identification of the coal strata, determination of their thickness, structure and depth. Correlation profiles constructed on the bases of geophysical diagrams also permit in many cases the determination of tectonic disturbances, their character and the synchronization of the coal strata. The comparing studies proved that the geophysical sampling for the determination of thickness, structure and location depth is more accurate than the mechanic sampling. In coal basins where the use of geophysical methods is more advanced, the qualitative determination of the coals by geophysical methods is at least as accurate as the determination by mining work. In the USSR, the evaluation of the thickness of the coal strata is estimated with an average error of minus 18% to the real thickness. In some deposits these subestimations range up to 55% (Pechora Basin). In some coal basins (Pechora, Southern Yakutia and Kusnetsk), the coal reserves are calculated only on the basis of results supplied by the geophysical sampling. Based on the practical importance of the geophysical sampling, the State Commission of Reserves of the USSR has established: "Utilization Conditions of geophysical sampling data for the calculation of coal reserves".

Card 3/6

R/010/60/011/011/001/001  
A231/A126

The application stage of geophysical methods ...

The State Commission determines that in case the geophysical sampling fulfills the respective conditions, it should be considered as a basic method for the determination of the necessary indexes for the calculation of the coal reserves. With regard to the importance and accuracy, the investigation of coal deposits by geophysical methods in the USSR presents three categories: 1 - Deposits where the use of geophysical methods is more advanced, obtaining by them: a) detection of thickness, structure and location depth of coal strata; and b) qualitative parameters of the coals. 2 - Deposits where the use of geophysical methods supplies with accuracy: a) detection of the thickness structure and location depth of coal deposits; and b) quality parameters; they are obtained by analyzing the samples taken with the sidewall sampler; 3 - Deposits where the use of geophysical methods is not sufficiently developed and no accurate data on the detection of thickness, structure and depth of strata can be given. But also in this situation, every drilling hole is geophysically sampled. The results obtained according to point 1 and 2, serve for the calculation of the coal reserves. On the basis of the results obtained, a method for the application of data supplied by geophysical sampling for the calculation of coal reserves has been worked out. In September 1958, M. S. Speranskiy forwarded to the Coal and Bituminous Slate Section of the Commission of Geological Experts at the State Commission of Reserves, his report: "Position of Geological Experts at the State Commission of Reserves, his report: "Pos-

The application stage of geophysical methods ...

sibilities and Conditions for the Use of Geophysical Sampling Data in the Calculation of Explored Coal Reserves". On the basis of this report, the State Commission of Reserves worked out and approved on November 15, 1958: "Application Conditions of Geophysical Sampling Data in the Calculation of Coal Reserves". The standards include the use of geophysical sampling procedures and the qualities which have to be fulfilled, as follows: The geophysical sampling is a basic method for the determination of some of the quantitative parameters of the coal in beds where the geophysical method proved to be equal, or superior to the mechanical sampling. In certain conditions it permits the identification of the presence of coal strata and the determination of the thickness, structure and location depth. The application degree of the data is determined by the particularities of the physical properties of the coals and rocks in their beddings and roofings; by the indices characterizing the thickness, structure and qualities of the coal; and by the accuracy of the results obtained by geophysical sampling. The degree of accuracy is determined by comparative studies between the results of the geophysical and mechanical samplings and of the mining works. The obligatory conditions for the use of data obtained by geophysical measurements on thickness, structure and "batimetry" of the strata are described. The advantages of the geophysical sampling against the mechanical sampling are: reduction of the costs by 30 - 50% per linear meter; doubling of the drilling speed; high

geological results and complete stratigraphic columns; more simple examination of the geophysical graphs. On the basis of the Soviet results, the author recommends the intensification of the application of geophysical methods in Rumania: Exchange of experience with the USSR and other socialist countries should be carried out. There are 2 tables and 6 Soviet-bloc references.

Impul'snyye tiratryony (Pulse Thyratrons) Moscow, Izd-vo "Sovetskoye radio",  
1958. 163 p. Number of copies printed not given.

Ed.: Ivamishko, N. D.; Tech. Ed.: Sveshnikov, A. A.

PURPOSE: This monograph is addressed to those engaged in the design of various installations in which pulse thyratrons are used, as well as to designers engaged in the development of pulse equipment.

COVERAGE: The monograph is concerned with the design and operating specifications of pulse thyratrons. The book contains data on research done on various physical processes and can be divided into three sections: 1) physical processes taking place in the thyratron during the pre-conduction part of the period; 2) physical processes taking place during the conduction part of the period; 3) physical processes taking place during the postconduction period. Some special problems associated with thyratron operation are discussed as well as pulse-thyratron manufacturing technique. The present work also deals with the results of research on the physical

Card 1/5

Pulse Thyratrons

593

processes taking place in thyratrons, obtained in development of the 1950 model TGII-130/10 high-frequency pulse thyratron. This thyratron has a new firing system which ensures high firing stability, short charge-buildup time, and operates at a pulse repetition rate of up to 30,000 cps. The following Soviet-produced equipment is discussed: the TGII-35/3, TGII-50/5 and TGII-130/10 thyratrons and the TGII-3/1 pulse thyratron all of them developed by the author; the type 25-I single beam oscilloscope; the TII-2 thyratron, mentioned as the first pulse thyratron to be developed in the Soviet Union; the TGII-260/12 thyratron; the TGI-0.3/12 thyratron (filled with krypton); and the TGZ-0.1/1.3 thyratron. Some of these thyratrons are enumerated in a table with additional variants of the TGII type. The author expresses thanks to Professor I. L. Kaganov for the supervision of the work, to Ya. S. Itsokhi, Doctor of Technical Sciences for valuable suggestions in reviewing the manuscript, and to Engineers M. V. Dmitriyeva and L. I. Freyberg for their help. There are 23 Soviet references (including 1 translation), 1 German, and 12 English.

TITLE: Superparamagnetism in austenitic steels

SOURCE: Fizika metallov i metallovedeniye, v. 20, no. 5, 1965, 793-795

TOPIC TAGS: austenitic steel, paramagnetism, magnetization, magnetic field, magnetic moment, metal physical property, metal physics

ABSTRACT: Superparamagnetism was studied in 40Kh2N20 and 50Kh2N22 austenitic steels in order to determine the average magnetic moments and dimensions of the local ferromagnetic ordering regions (clusters). Magnetization curves are given both for constant magnetic fields and strongly changing ones. Sample dimensions were 1 mm (diameter) and 10 mm (length). The data showed that the experimental portions of the magnetization curves, corresponding to the values of the fields causing martensitic transformation in these steels, can be described by the Langevin function

L 14991-66

ACC NR: AP5028570

$$\frac{I}{I_s} = \frac{\sigma}{\sigma_0} = L \left( \frac{MH}{kT} \right). \quad (1)$$

where  $k$  is Boltzman's constant,  $T$  is the absolute temperature,  $M$  is magnetic moment of the superparamagnetic particle and  $I_s$  is saturation magnetization of the sample. Satisfactory agreement of the experimental and calculated curves exhibit the utility of equation (1) for calculating the magnetic moments of particles. Two boundary cases were considered, corresponding to the conditions when  $MH/kT \ll 1$  (weak field) and  $MH/kT \gg 1$  (strong field). Equation (1) for the case when  $MH/kT \ll 1$  reduces to

$$\frac{I}{I_s} = \frac{NM^2}{3k} \frac{H}{T},$$

where  $N$  is the number of particles per  $\text{cm}^3$ ; for the case when  $MH/kT \gg 1$ , the following was applicable:

$$\frac{I}{I_s} = \frac{\sigma}{\sigma_0} = 1 - \frac{kT}{M \cdot H}.$$

Card 2/3

L 14991-66

ACC NR: AP5028570

The average dimensions of the particles were calculated to be  $d = 10$  angstrom. The conclusions substantiated the authors' hypothesis of the presence of paramagnetism in austenitic steels based on the calculated magnetic moments and the impossibility of attaining saturation even in fields as high as  $150 \cdot 10^3$  oersted. TITLE: Determining the latent heat of martensite conversion induced in steel by a magnetic field

SOURCE: Fizika metallov i metallovedeniye, v. 21, no. 3, 1966, 436-441

79

B

TOPIC TAGS: magnetic effect, martensitic transformation, constant magnetic field, pulsed magnetic field, calorimetry, nickel steel, high temperature phenomenon

ABSTRACT: The authors study the thermal phenomena which accompany martensite conversion induced by a magnetic field in steels. The study confirms the previously known fact of stepwise formation of isolated martensite bodies and indicates that a similar mechanism of martensite conversion takes place regardless of the physical causes underlying the  $\gamma \rightarrow \alpha$  conversion. A method is proposed for determining the latent heat of martensite conversion due to the effect of the magnetic field in 40Kh2N20 and 58Kh4N8S3M steels. The chemical composition of these steels is given in the table below. It is shown that both pulsed and constant magnetic fields may initiate this conversion. The advantages of the proposed method for determining the latent heat of austenite-to-martensite conversion in a magnetic field are discussed in comparison with the calorimetric method.

field - magnetization of austenitic steel in a strong pulsed magnetic

SOURCE: Fizika metallov i metallovedeniya, v. 10, no. 6, 1985, p. 821-827

TOPIC-TACS: austenitic steel, martensitic transformation, magnetic behavior, metal physics, thermodynamic analysis, low temperature phenomena

ABSTRACT: Magnetization of austenitic steel 15Kh2N22, 30Kh2N22 and 4Kh2N20 was studied. The martensitic transformation took place under the action of a strong magnetic field. The dependence of magnetization of the sample on the value of the magnetic field impulse was measured at room, as well as the dependence of magnetization on frequency. The critical frequency was given by  $\omega_k = 55 + 5f^{1/2}$ , and the validity of the relation  $\omega_k/(S_2 - S_1) = \text{constant}$  was established, where demagnetization of the sample from one austenite  $S_1$  and  $S_2$

L 6044-65

ACCESSION NR: AP5016527

values of the entropy of both  $\alpha$  and  $\gamma$  phases. The transition to transformation caused by the strong magnetic field did not proceed at one definite field, but in a series of jumps, from which the first (at  $H = H_c$ ) appeared the greatest. The critical field  $H_c$ , at which the most intensive martensitic burst started, depended weakly on the duration of the magnetic impulse. Critical field independently on temperature was in accord with the thermodynamic theory of phase transformation of the first order. Orig. act. has 7 figures.

The composition of the precipitate deposited in soda-production apparatus and measures for avoiding it. II. V. E. Voronchikhin. J. Chem. Ind. (U.S. S. R.) 16, No. 8, 17-21 (1957); U. S. A. 3,23041. The deposit in various parts of the app. consists of varying proportions of  $\text{CaCO}_3$  and  $\text{MgCO}_3$ , mixed with  $\text{NaCl}$  and  $\text{Na}_2\text{CO}_3$  or  $\text{NaHCO}_3$ . Fine crystals of  $\text{CaCO}_3$  do not tend to accumulate, but may collect around dust particles to form thick incrustations. Therefore, the liquid should be covered at all times. Mg compds. cause incrustations most actively, and Mg should be removed as completely as possible. Pptd.  $\text{Mg(OH)}_2$  is as bad as sol. Mg salts if it is allowed to circulate with the brine, since it redissolves and ppts. as  $\text{MgCO}_3$ . H. M. Leicester

**PROCESSES AND PROPERTIES INDUCED**

The preparation of sodium hydroxide from soda solutions by granular lime. V. E. Voronchikhin and G. S. Plakhotnyuk. *J. Chem. Ind. (Moscow)* 1934, No. 10, 33-9.—When soda soaps are treated with  $\text{Ca}(\text{OH})_2$ , the  $\text{CaCO}_3$  formed takes too long to settle. Addition of  $\text{Fe}_2\text{O}_3$  or starch to the soap, increases the rate of settling. Better results are obtained if granulated lime is added to the soda with mech. stirring. The best lime grains are prep'd. by triturating slaked lime with strong soda soln. and allallowing the paste to stand in a closed vessel. The mass soon becomes solid and can be easily broken up into small grains. H. M. Lester

H. M. LEISERSON

PROPERTIES AND PROBLEMS (N-1)

*Cla*

The composition of the precipitate found in soda-production apparatus and measures for avoiding it. V. B. Vurichchikin, *J. Chem. Ind. (U.S. S. R.)* 13, 14 (1937).  
The ppt. in the still is anhyd.  $\text{CaSO}_4$ . Its presence there can be avoided by raising the temp. of the app. just before the still to 110-115°, thus pptg. anhyd.  $\text{CaSO}_4$  at that point, or by lowering the temp. of the whole app. to 93°, where  $\text{CaSO}_4 \cdot \text{Na}_2\text{O}$  will ppt. H. M. Leibster.

The preparation of sodium hydroxide from soda ash-  
tion by granular lime. V. N. Vysotskikh. J. Chem.  
Ind. (Moscow) 13, 164 (1910); cf. Chem. Ztg., 1910,  
When 200 g. stone lime is added rapidly to 500 g. of  
Ca(OH)<sub>2</sub>, the Ca(OH)<sub>2</sub> product is dense and settles in the  
soil, at a moderate speed. If cold H<sub>2</sub>O is added rapidly,  
the Ca(OH)<sub>2</sub> is porous, but settles slowly. The best time  
for the prep. of NaOH is obtained by slow addition of cold  
H<sub>2</sub>O. The Ca(OH)<sub>2</sub> which is formed is porous and settles  
rapidly. H. M. Leicester

1ST AND 2ND ORDERS	FOURTH AND FIFTH ORDERS				
Sodium bicarbonate. V. E. Koronflikas. U.S.P. No. 2,619,954, Aug. 31, 1946. Cryst. Na <sub>2</sub> CO <sub>3</sub> .10H <sub>2</sub> O is made to cascade in a vertical chamber provided with fixed liquid shelves. Countercurrent to the cascading crystals passes CO <sub>2</sub> or its melt, with dry air preheated to 60°. NaHCO <sub>3</sub> is formed and simultaneously dried. To prevent caking, the incoming Na <sub>2</sub> CO <sub>3</sub> .10H <sub>2</sub> O is mixed with freshly obtained NaHCO <sub>3</sub> . M. Howell

Repeating (1)action of the last-quoted stage in the production of caustic, V. H. Voronchikov, *J. Russ. Chem. Ind.* (U. S. S. R.) 17, No. 11, 291 (1910).—When the  $\text{CaCO}_3$ , pptd. by treating  $\text{Na}_2\text{CO}_3$  with  $\text{CaO}$ , is ignited to  $\text{CaO}$ , which is used again, the quality of the  $\text{CaO}$  gradually falls off, and after 8–10 ignitions, it must be discarded. The  $\text{CaCO}_3$  from ignited  $\text{CaO}$  settles more rapidly from  $\text{NaOH}$  soln., but Al compounds, tend to accumulate in the  $\text{NaOH}$ .  
H. M. LeCester

Preservation of the mixture as a new method for  
intensifying the ammonia-soda process. V. I. Vorot-  
chikhin. Chem. Ind. (U. S. S. R.) 18, No. 1, 21 (1960).—Part of the liquid which has been through the  
process and still contains solid crystals is mixed with the  
salt entering the process. This increases the efficiency  
of the method. H. M. Leicester

TITLE: Automatic regulator for pump shaft rotation rate. Class 60, No. 1163997

SOURCE: Byulleten' izobretenij i tovarkh. naikov, No. 10, 1960

TOPIC TAGS: pneumatic system, pump, shaft

ABSTRACT: This Author Certificate presents an automatic regulator for the shaft rotation speed of a pump with a pneumatic drive. The pump consists of a balanced piston slide valve and an elastic diaphragm rigidly connected to it by a spring-loaded stem and placed in a closed chamber (see Fig. 1 on the enclosure).

To control the rotation rate of the pneumatic drive of the pump, the chamber with the diaphragm is connected to the discharge line of the pump. Orig. art. has 1 figure.

TITLE: A Bellows Type Regulation Valve for Operation at Pressures  
up to 150 atm

PERIODICAL: Pribory i tekhnika eksperimenta, 1960, No 3, p 149

ABSTRACT: In an earlier paper (Ref 1), R. A. Alikhanov described the design of a valve of very low weight which permits continuous regulation of small quantity gas flows at pressures up to 4 atm. This valve has been modified by the authors of this paper to permit regulating gas flows with pressures up to 150 atm. This bellows type valve is of small dimensions and due to a special configuration of the needle the initial gas flow can be regulated between 0.03 and 0.05 cm<sup>3</sup>/min at normal pressure. Up to the maximum flow, which is 2 to 3 cm<sup>3</sup>/min, the flow rate can be regulated with an accuracy of 0.1 to 0.2 cm<sup>3</sup>/min for a pressure gradient of 150 atm. In the case of lower pressure gradients the accuracy of the regulation can be made higher. The valve was tested with hydrogen up to pressures of 150 atm.

TITLE:	The specific heat of pure substances close to the critical point			15
SOURCE:	Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 43, no. 3, 965, 1961-1964			
TOPIC TAGS:	argon, nitrogen, oxygen, specific heat measurement			
ABSTRACT:	The specific heat of argon at critical density was measured very carefully in temperature intervals down to approximately 0.02K. Since there were considerable discrepancies in the literature on the critical density of argon, measurements were made at several densities close to critical. The quantity of gas used at the calorimeter was determined by weighing, and the measurement error exceeded 0.3%. Tables are given for densities of 0.533, 0.534 and 0.535 g/cm <sup>3</sup> . It was found that 0.533 g/cm <sup>3</sup> is closest to the critical density. Curves are given for curves of specific heat versus temperature for rarefied gases at different densities. AUTHORS: Voronel', A. V., Giterman, M. Sh.

TITLE: The Hydrostatic Effect<sup>1</sup> Near the Critical Point of a LiquidPERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, 1960,  
Vol. 39, No. 4(10), pp. 1162 - 1163

TEXT: Near the critical point of a pure substance, its compressibility increases to an unlimited extent; therefore, already a slight change of pressure, caused by the pressure of the upper layers of the liquid upon the lower ones, may be of essential importance. For this case, the authors theoretically investigated the curves of state  $p(V)$  and  $\rho(V)$ . The change in pressure with height is given by  $dp = (\mu g/V)dh$ , where  $V$  is the specific volume at the height  $h$ , and  $\mu$  is the molecular weight. If  $p$  and  $V$  deviate only little from the critical values, then, if  $T = T_c$ ,  $-dh/dV = (B/2\mu g)V(V-V_c)^2$  and  $V = V_c - \alpha(h-h_0)^{1/3}$  with  $\alpha = (6\mu g/BV_c)^{1/3}$ , where  $h_0$  denotes the integration constant which gives the height at which

the critical conditions are satisfied;  $B = (\partial^3 p / \partial V^3)_T$ . The mean specific volume in the entire vessel is experimentally measurable, and so is the pressure at a certain level. If  $p_o$  predominates at  $h=0$ , one obtains

$V_{\text{mean}} = \frac{1}{H} \int_0^H V(h) dh = V_c - \frac{3}{4H} [(H-h_o)^{4/3} - h_o^{4/3}]$ . A numerical estimate shows that for all substances at  $0 < h_o < H$  and  $H \sim 10$  cm,  $(p_o - p_c)/p_o \sim 10^{-4} - 10^{-5}$ , i.e.,  $p_o$  may be put equal to  $p_c$ . As  $B$  is very small,  $V_{\text{mean}}$  may be expected to deviate considerably from  $V_c$  at  $p_o \approx p_c$ .  $|V_{\text{mean}} - V_c|$  attains its maximum value at  $h_o = 0$  and  $h_o = H$ . In the case of coexistence of liquid and vapor, the  $p(V)$  and  $T(V)$  curves, respectively, show a straight part of width  $\Delta = \frac{3}{2} (6\mu g H / B V_c)^{1/3}$ . This curve is, besides the ordinary curve, shown in a diagram. Such a shape has actually been observed in the case of xenon, ethane, and ethylene. For xenon, the ratio of the vessel

heights in two experiments was  $H_1/H_2 = 19 \text{ cm}/13 \text{ cm} = 1.46$  and  $(\Delta_1/\Delta_2)^3 = 1.57$ , and for ethylene  $H_1/H_2 = 2.5$  and  $(\Delta_1/\Delta_2)^3 = 2.56$ ; these data agree well with the formula for  $\Delta$ . From an experimental determination of  $\Delta$  it is possible to determine  $B$  from this formula. Thus one obtains for xenon, if  $H = 19 \text{ cm}$ ,  $\Delta = 0.20 \text{ g.cm}^{-3}$ ,  $B \approx 4 \cdot 10^{-5} \text{ atm/cm}^9$ . The authors thank M. Ya. Azbel' for discussions. element [see illustration] is an annealed platinum wire 0.05 mm in diameter wound with 0.1 pitch on a helical platinum core 0.2 to 0.3 mm in diameter. The core is insulated with a thin film. There is no thermal stress, because the core and the winding are made of the same material. The specific heat of the thermometer is a function of the properties of the insulating film. The thermometer is sealed in a copper housing filled with dry helium (10 to 150 mm Hg). A variant designed and tested at the Institute had a core insulated with a B-2 glue film polymerized for several hours at 140°C. The thermometer was 11 mm in length and 4 mm in diameter, weighed ~ 0.5 g.

and had a resistance at the triple point of water of  $R_0 = 32,630$  ohm. It was periodically cooled by liquid nitrogen at  $-195^{\circ}\text{C}$  and heated by water at  $+100^{\circ}\text{C}$  for two months. After one week a stable resistance with an accuracy of  $\pm (5-10) \cdot 10^{-4}$  ohms was established, which corresponds to a temperature of 0.003 to 0.005°C. The dimensions of the thermometer could be further reduced and its stability improved by using improved heat-resistant materials for core insulation. The frameless design of the thermometer permits a wide variation in shape.

TITLE: Measurement of the specific heat  $C_v$  of argon near its critical point

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 43, no. 2(8), 1962, 728-729

TEXT: The dependence of the specific heat of argon on the temperature near the critical point was studied with the aid of a technique developed by A. V. Voronel' and P. G. Strelkov (PTE, 6, 111, 1960). Near the critical point (transition from the two-phase system liquid-vapor into a homogeneous system) at a density of  $0.521 \text{ g/cm}^3$ ,  $C_v$  tends to infinity.

The limit of the difference between the specific heats of the heterogeneous and homogeneous phases can be regarded as a jump in specific heat. It amounts to 20 cal/mole.deg. The jump occurred at  $150.5^\circ\text{K}$  (critical temperature  $150.7^\circ\text{K}$ ). There are 2 figures.

TOPIC TAGS:	nitrogen, specific heat, critical point, temperature dependence, thermogram		
ABSTRACT:	In connection with the discussion concerning the analytic form of the specific heat singularity near the critical point (M. E. Fisher, Phys. Rev., 136, A1599, 1964; M. E. Fisher, J. of Mathem. Phys., 5, 944, 1964), certain measurement results of the specific heat of nitrogen near the critical point are presented for an extended temperature range within 0.01C of $T_c$ . The experimental errors are less than 5%. The data obtained indicate a logarithmic		2
Card 1/2			

L 28074-66

ACC NR: AP6014028

2

dependence of the specific heat on temperature for  $T > T_c$  and  $T < T_c$ ; the slopes of curves are the same from the left and right, that is, for  $T > T_c$  and  $T < T_c$ , and the finite change  $\Delta C_V = \lim (C_V^+ - C_V^-)$  for  $1T \rightarrow T_c, 1 \rightarrow 0$  remains the same, in agreement with an earlier work M. Ya. Azbel, A. V. Voronel', M. Sh. Giterman, ZhETF, 46, 673, 1963). Since the value of the  $T_c$  is important for interpreting the results, its value has been determined with an accuracy of 0.001°C by a method similar to the thermographic one. In this connection it has been found that by using the results of a previous paper (Yu. R. Chashkin, V. G. Gorbunova, A. V. Voronel', ZhETF, 49, 433, 1965), the total amount of impurities in the gas can be determined with greater reliability accurate to 0.02%. The authors thank V. Vaks and A. Larkin for discussing certain problems. Orig. art. has: 6 figures, 2 formulas, and 1 table. [Based on authors' abstract]

TITLE: Contribution on a Thermodynamic Scale for High Pressures

PERIODICAL: Fizika metallov i metallovedeniye, 1960, Vol 9, Nr 2,  
pp 174 - 177 (USSR)

ABSTRACT: The author points out that pairs of substances can be found whose melting-point curves cross on the pressure-temperature plane (at the intersection both melt at the same temperature and pressure). The figure shows such curves for tin, phosphorus, carbon tetrachloride, silicon tetrachloride, phenol, chloroform and argon. The pressure in an apparatus where melting of two substances occurs simultaneously could thus be considered as a reference pressure to which a value obtained by calculation from the melting-point curve equations could be assigned. For this the author recommends one of his forms (Ref 2) of Simon's equation. This has a constant whose physical significance is clear from Salter's (Ref 3) work. He shows an arrangement of the equation from which all required parameters and pressure values can be found by

Card1/2

S/126/60/009/02/003/033

F111/E335

Contribution on a Thermodynamic Scale for High Pressures

successive approximations from measurements of temperature (not pressure directly). The validity of the method depends on the applicability of Simon's equation, which is wide; it does not depend on possible variations of the constant of this equation along the melting-point curve and this variation can be studied by choosing a number of triangles shown in the figure.

AUTHOR: Azbel', M. Ya.; Voronel', A. V.; Giterman, M. Sh.

TITLE: Contribution to the theory of the critical point

SOURCE: Zhurnal eksper. i teor. fiz., v. 46, no. 2, 1964, 673-676

TOPIC TAGS: critical point, free energy, equation of state, co-existence curve, phase equilibrium, free energy, specific heat, singularity, critical volume

ABSTRACT: In view of the discrepancy with ordinary theory displayed by the experimental results of the VNIIIFTRI Thermodynamics Laboratory (M. I. Bagatskiy, A. V. Voronel', V. G. Gusak, ZhETF, v. 43, 728, 1962; A. V. Voronel', Yu. R. Chashkin, V. A. Popov, V. G. Simkin, ZhETF, 45, 828, 1963), where a logarithmic singularity was observed for the temperature dependence of the specific heat  $\Theta$  near the critical volume, the authors propose a new theory in which the form of the free energy near the critical point agrees with these experimental data. In both the existing and modified theories the order of the smallest nonvanishing derivative of the pressure with respect to the volume at the critical point determines

card 1/2

ACCESSION NR: AP4019235

uniquely the form of the phase-equilibrium point near the critical point, namely proportionality of the relative temperature to the relative volume squared. Several ways of checking the consequences due to the presence of the singularity at the critical point will be treated in a future article. Orig. art. has: 6 formulas.
